## Convolutional Neural Network (CNN)

**H.M. Samadhi Chathuranga Rathnayake**

M.Sc in CS (SU), PG.Dip in SML (Othm), PG.Dip in HRM (LRN), B.Sc (Hons) in IS (UOC), B.Eng (Hons) in SE (LMU),  
P. Dip EP & SBO (ABE), Dip SE, Dip IT, Dip IT & E-Com, Dip B.Mgt, Dip HRM, Dip Eng

# Introduction to CNN

- Convolutional neural networks were invented by Yann LeCun, who also serves as director of Facebook's AI Research Group.
- In 1988, he created the first convolutional neural network, known as LeNet.
- For character recognition tasks like reading zip codes and numbers, LeNet was employed.
- Have you ever wondered how object detection helps to construct self-driving cars, how facial recognition works on social media, or how disease identification is done using visual imaging in healthcare?
- All of this is made possible by convolutional neural networks (CNN).

# Introduction to CNN

- Think there's an image of a bird, and you want to identify whether it's really a bird or some other object.
- The first thing you do is feed the pixels of the image in the form of arrays to the input layer of the neural network (multi-layer networks used to classify things).
- The hidden layers carry out feature extraction by performing different calculations and manipulations.
- There are multiple hidden layers like the convolution layer, the ReLU layer, and pooling layer, that perform feature extraction from the image.
- At the end, there's a fully connected layer that identifies the object in the image.

# Introduction to CNN

# Introduction to CNN

- In CNN, every image is represented in the form of an array of pixel values.

# Introduction to CNN

- In CNN, every image is represented in the form of an array of pixel values.

# Introduction to CNN

- In CNN, every image is represented in the form of an array of pixel values.

# Convolutional Operations

- Any convolutional neural network's foundation is the convolution process.
- Let's examine the convolution operation using two 1-dimensional matrices, a and b.

- This process continues until the convolution operation is complete.

# Layers of CNN

- A convolution neural network has multiple hidden layers that help in extracting information from an image. The four important layers in CNN are:
  - Convolution layer
  - ReLU (Rectified Linear Unit) layer
  - Pooling layer
  - Fully connected layer

# Convolution Layer

- The process of removing useful elements from an image begins with this.
- Multiple filters work together to perform the convolution action in a convolution layer.
- Each image can be thought of as a matrix of pixel values.

# Convolution Layer

- **Padding** virtually extends the matrix to cater to border values as described in the image below. The pink layer isn't a part of the feature matrix, but helps in convolution.
- In below example padding is taken as 0.

# ReLU layer

- ReLU stands for the rectified linear unit.
- Once the feature maps are extracted, the next step is to move them to a ReLU layer.
- ReLU performs an element-wise operation and sets all the negative pixels to 0.
- It introduces non-linearity to the network, and the generated output is a rectified feature map.

# ReLU layer

# Pooling Layer

- Pooling is a down-sampling operation that reduces the dimensionality of the feature map.
- The rectified feature map now goes through a pooling layer to generate a pooled feature map.

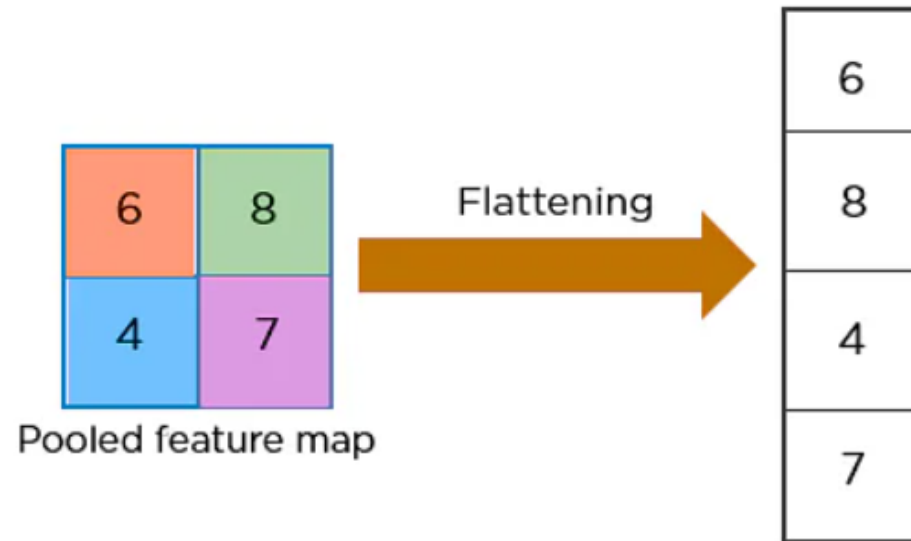

# Pooling Layer

- To distinguish distinct portions of the image, such as edges, corners, bodies, feathers, eyes, and beak, the pooling layer employs a variety of filters.

# Flattening

- The next step in the process is called flattening.
- Flattening is used to convert all the resultant 2-Dimensional arrays from pooled feature maps into a single long continuous linear vector.

# Fully Connected Layer

- The flattened matrix is fed as input to the fully connected layer to classify the image.

# Summary

- The pixels from the image are fed to the convolutional layer that performs the convolution operation
- It results in a convolved map
- The convolved map is applied to a ReLU function to generate a rectified feature map
- The image is processed with multiple convolutions and ReLU layers for locating the features
- Different pooling layers with various filters are used to identify specific parts of the image
- The pooled feature map is flattened and fed to a fully connected layer to get the final output

# Summary
